

References & Pointers

Recap Variables & Memory

- If a variable is declared in the code, a certain amount of memory is allocated for it in the computer's memory

Code level

```
int x = 12;
```

Physical memory level

Address level

0x7f

Address in memory
of variable x

Value level

12

Value of variable x

Variable name level

x

Recap Variables & Memory

- The amount of memory allocated depends on the variable's type, e.g., int32, int64, string, multiple data types in a user-defined class, ...

Code level

```
int x = 12;
```

Physical memory level

Address level

0x7f

Address in memory
of variable x

Value level

12

Value of variable x

Variable name level

x

Recap Variables & Memory

- The allocated memory block is clearly identified by an address and associated with the corresponding variable in code

Code level

```
int x = 12;
```

Physical memory level

Address level

0x7f

Address in memory
of variable x

Value level

12

Value of variable x

Variable name level

x

The Reference Type

- A variable of type **reference to a data type** is an **alias** of another variable, **it refers to an existing** variable

Code level

```
int x = 12;  
  
int& ref = x;
```

Physical memory level

Address level

0x7f

Address in memory
of variable x

Value level

12

Value of variable x

Variable name level

x, ref

The Reference Type

- A variable of type **reference to a data type** is declared by adding the address-of-operator “&” to the data type like so:
 - `int&`, `float&`, `myObject&`, `ofTexture&`, ...

Code level

```
int x = 12;  
  
int& ref = x;
```

Physical memory level

Address level

0x7f

Address in memory
of variable x

Value level

12

Value of variable x

Variable name level

x, ref

The Reference Type

- A reference variable is an additional name to an existing variable,
- It is not specified in C++ whether actual memory is being allocated for a variable of type reference

Code level

```
int x = 12;  
  
int& ref = x;
```

Physical memory level

Address level

0x7f

Address in memory
of variable x

Value level

12

Value of variable x

Variable name level

x, ref

The Reference Type

- This is why a reference variable MUST always be initialized with the object it refers to
- A variable of type reference cannot stand alone

Code level

```
int x = 12;
```

```
int& ref = x;
```

```
int& refAlone;
```

Physical memory level

Address level

0x7f

Address in memory
of variable x

Value level

12

Value of variable x

Variable name level

x, ref

The Reference Type

- Any change to a variable of type reference will **always result** in a change of the original variable
- Reference variables can be used just like a normal variable

Code level

```
int x = 12;           ref += 5;
                        => // x (and ref)
int& ref = x;         // will both be 17
```

Physical memory level

Address level

0x7f

Address in memory
of variable x

Value level

12

Value of variable x

Variable name level

x, ref

The Reference Type by Example

- Manipulating the reference variable directly affects the referenced variable & vice versa

```
43 int x = 5;
44 int &z = x; // z is another name for x
45 int &y;      // Error: reference must be initialized!
46
47 cout << x << endl; // -> prints 5
48 cout << z << endl; // -> prints 5
49
50 z = 9;      // same as x = 9;
51
52 cout << x << endl; // -> prints 9
53 cout << z << endl; // -> prints 9
```

Benefits of References

- Reference types support efficient data handling
- In particular, when used as function parameters they allow to access data without having
 - to initialize new variables and
 - to copy the variable's values
- Reference types support all kinds of data manipulation whenever the referenced variable cannot be accessed directly

The Pointer Type

- A variable of type **pointer to a data type** is storing the address value of an associated variable using **&varName**

Code level

```
int x = 12;  
  
int* ptr = &x;
```

Physical memory level

Address level	0x7f Address in memory of variable x	0x2f Address in memory of variable ptr
Value level	12 Value of variable x	0x7f Value of variable ptr
Variable name level	x	ptr

The Pointer Type

- A variable of type **pointer to a data type** is declared by adding the operator “*****” to the data type like so:
 - `int*`, `float*`, `myObject*`, `ofTexture*`, ...

Code level

```
int x = 12;  
  
int* ptr = &x;
```

Physical memory level

Address level	0x7f Address in memory of variable x	0x2f Address in memory of variable ptr
Value level	12 Value of variable x	0x7f Value of variable ptr
Variable name level	x	ptr

The Pointer Type

- The value of the variable the pointer points to can be de-referenced using the **dereferencing-operator** “*” which must be put in front of the variable’s name like so “*ptr”

Accessing the value of the
variable ptr points to

Code level

```
int x = 12;          cout << *ptr << endl;
                        =>
int* ptr = &x;      // prints 12
```

Physical memory level

Address level	0x7f	Address in memory of variable x	0x2f	Address in memory of variable ptr
Value level	12	Value of variable x	0x7f	Value of variable ptr
Variable name level	x		ptr	

The Pointer Type

- The value of the variable the pointer points to can be de-referenced using the **dereferencing-operator** “*” which must be put in front of the variable’s name like so “*ptr”

Code level

```
int x = 12;
```

=>

```
int* ptr = &x;
```

Changing the variable ptr points to

```
*ptr += 5;
```

```
// x (and *ptr)
```

```
// will both be 17
```

Physical memory level

Address level

0x7f

Address in memory
of variable x

0x2f

Address in memory
of variable ptr

Value level

12

Value of variable x

0x7f

Value of variable ptr

Variable name level

x

ptr

The Pointer Type

- A variable of type **pointer to a data type** can also be used to store the address of a **newly (or dynamically) allocated** block of memory using **new <data type>()**

Code level

```
int x = 12;  
  
int* ptr = new int();
```

Physical memory level

Address level	0x7f Address in memory of variable x	0x2f Address in memory of variable ptr
Value level	12 Value of variable x	0x8d Address of some memory block
Variable name level	x	ptr

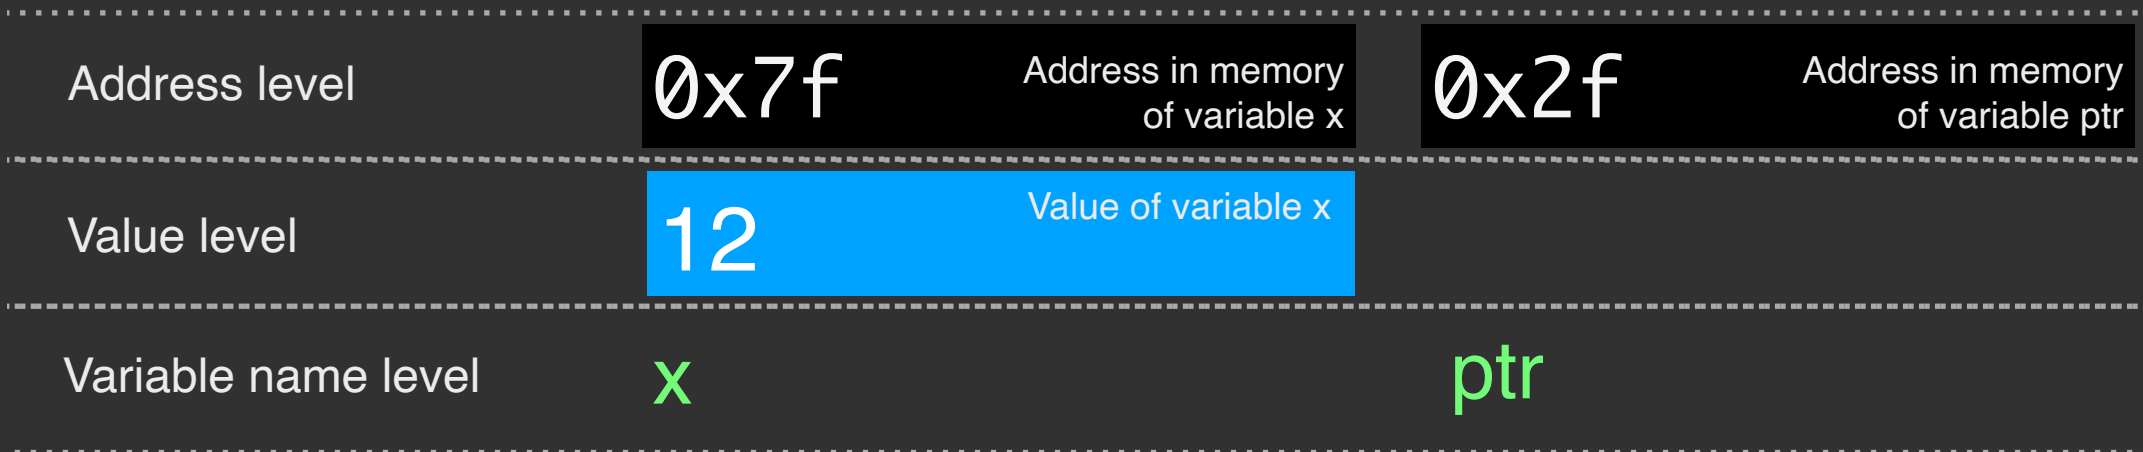

The Pointer Type

- Using variable of type **pointer to a data type** can be tricky because the memory that was allocated dynamically with **new** must also be **de-allocated** once the program ends with **delete**

Code level

```
int x = 12;  
// . . .  
delete ptr;
```

Physical memory level

The Pointer Type

- To ensure that pointers do not point into some un-allocated memory block they should always be initialized to a variable or **nullptr**

Code level

```
int x = 12;  
  
int* ptr = nullptr;
```

Physical memory level

Address level	0x7f	Address in memory of variable x	0x2f	Address in memory of variable ptr
Value level	12	Value of variable x	0x00	nullptr
Variable name level	x		ptr	

Benefits of Pointers

- Pointers in C++ have various application areas
- They are primarily used when the application program has to deal with **dynamic memory allocation**, i.e.,
 - the size of the memory that will be required to store the data can only be allocated during run-time
 - the size of the data is not known at compile-time
- Such data could be images, audio, user input

References & Pointers Compared

- Similar at first glance, there is a clear difference between the types:
 - References refer to the object they were initialized with
 - Pointers are individual objects that allow to manipulate memory

```
int x = 12;
```

```
int& ref = x ;      int* ptr = &x;
```

Address level	0x7f	Address in memory of variable x	0x2f	Address in memory of variable ptr
Value level	12	Value of variable x	0x7f	Value of variable ptr
Variable name level	x, ref		ptr	

References & Pointers by Example

- Let's swap some values! We use two functions with different types of arguments to do the same thing:

```
8  #include <iostream>
9  using namespace std;
10
11 // Function Prototypes(required in C++)
12
13 // here * is not the dereference operator!
14 // int * -> indicates that the argument is a pointer pointing to an int
15 void p_swap(int *, int *);
16
17 // int & -> indicates the arguments are treated as references to ints
18 // here changing the value of an function argument will change
19 // the value of the variable initialized outside the function
20 void r_swap(int&, int&);
21
```

References & Pointers by Example

- In this program, the initially declared integer values are swapped in two different ways:

```
22
23 int main (void) {
24     int v = 5, x = 10;
25     cout << "v: " << v << " x: " << x << endl; // prints v: 5 x: 10
26     p_swap(&v, &x);                               // passing in addresses (pointers)
27     cout << "v: " << v << " x: " << x << endl; // prints v: 10 x: 15
28     r_swap(v, x);                                   // passing in values
29     cout << "v: " << v << " x: " << x << endl; // prints v: 5 x: 10
30     return 0;
31 }
32
```

References & Pointers by Example

- Pointer Swap
 - Changing the values at memory address level requires to pass pointers that are being dereferenced

```
34 // uses the dereference operator to access the values
35 // belonging to the addresses passed in, changing v and x
36 void p_swap(int* a, int* b)
37 {
38     int temp;
39     temp = *a; // store dereferenced value of a (5)
40     *a = *b;   // assign value at memory adress a to b (10)
41     *b = temp; // assign stored value to b (5)
42 }
43
```

References & Pointers by Example

- Reference Swap
 - Changing the values of the external input variables v and x without using memory addresses at all

```
43
44 // reference swap:
45 // swaps the values of the original variables passed in
46 // without returning anything, changing v and x back
47 void r_swap(int& a, int& b)
48 {
49     int temp;
50     temp = a;    // store reference a to temp (10)
51     a = b;       // assign reference of b to a (5)
52     b = temp;    // assign original reference a to b (10)
53 }
54
```

Take Away

- References and pointers are dedicated data types in C++ introduced to increase the efficient management of data
- References should be considered as referring to another object, they are no individual object of themselves
- Pointers are pointing to memory addresses of variables and objects, they are individual objects that support the dynamic and manual allocation and management of data
